2 × 1.4 W BTL audio amplifiers with digital volume control and headphone sensing

TDA8552T; TDA8552TS

FEATURES

- One pin digital volume control (for each channel)
- Volume setting with up/down pulses
- Auto repeat function on volume setting
- Headphone sensing
- Maximum gain set by selection pin
- Low sensitivity for EMC radiation
- Internal feedback resistors
- Flexibility in use
- Few external components
- Low saturation voltage of output stage
- Standby mode controlled by CMOS compatible levels
- Low standby current
- No switch-on/switch-off pops
- High supply voltage ripple rejection
- Protected against electrostatic discharge
- Outputs short-circuit safe to ground, V_{DD} and across the load
- Thermally protected.

APPLICATIONS

- Portable consumer products
- Notebook computers
- Communication equipment.

ORDERING INFORMATION

TYPE NUMBER	PACKAGE		
	NAME	DESCRIPTION	VERSION
TDA8552T	SO20	plastic small outline package; 20 leads; body width 7.5 mm	SOT163-1
TDA8552TS	SSOP20	plastic shrink small outline package; 20 leads; body width 4.4 mm	SOT266-1

GENERAL DESCRIPTION

The TDA8552T is a two channel audio power amplifier that provides an output power of $2 \times 1.4 \text{ W}$ into an 8Ω load using a 5 V power supply. The circuit contains two BTL power amplifiers, two digital volume controls and standby/mute logic. Volume and balance of the amplifiers are controlled using two digital input pins which can be driven by simple push-buttons or by a microcontroller.

Using the selection pin (GAINSEL) the maximum gain can be set at 20 or 30 dB. The headphone sense input (HPS) can be used to detect if a headphone is plugged into the jack connector. If a headphone is plugged into the jack connector the amplifier switches from the BTL to the SE mode and the BTL loudspeakers are switched off. This also results in a reduction of quiescent current consumption.

The TDA8552T is contained in a 20-pin small outline package. For the TDA8552TS, which is contained in a 20-pin very small outline package, the maximum output power is limited by the maximum allowed ambient temperature. More information can be found in Section "Thermal design considerations". The SO20 package has the four corner leads connected to the die pad so that the thermal behaviour can be improved by the PCB layout.

PINNING

SYMBOL	PIN ⁽¹⁾	DESCRIPTION
GND1	1	ground 1, substrate/leadframe
OUT2+	2	positive loudspeaker terminal output channel 2
V _{DD1}	3	supply voltage 1
HPS	4	digital input for headphone sensing
MODE	5	digital trinary input for mode selection (standby, mute and operating)
UP/DOWN1	6	digital trinary input for volume control channel 1
UP/DOWN2	7	digital trinary input for volume control channel 2
V _{DD2}	8	supply voltage 2
OUT2-	9	negative loudspeaker terminal output channel 2
GND2	10	ground 2, substrate/leadframe
GND3	11	ground 3, substrate/leadframe
OUT1+	12	positive loudspeaker terminal output channel 1
V _{DD3}	13	supply voltage 3
GAINSEL	14	digital input for gain selection
IN2	15	audio input channel 2
SVR	16	half supply voltage, decoupling ripple rejection
IN1	17	audio input channel 1
V _{DD4}	18	supply voltage 4
OUT1-	19	negative loudspeaker terminal output channel 1
GND4	20	ground 4, substrate/leadframe

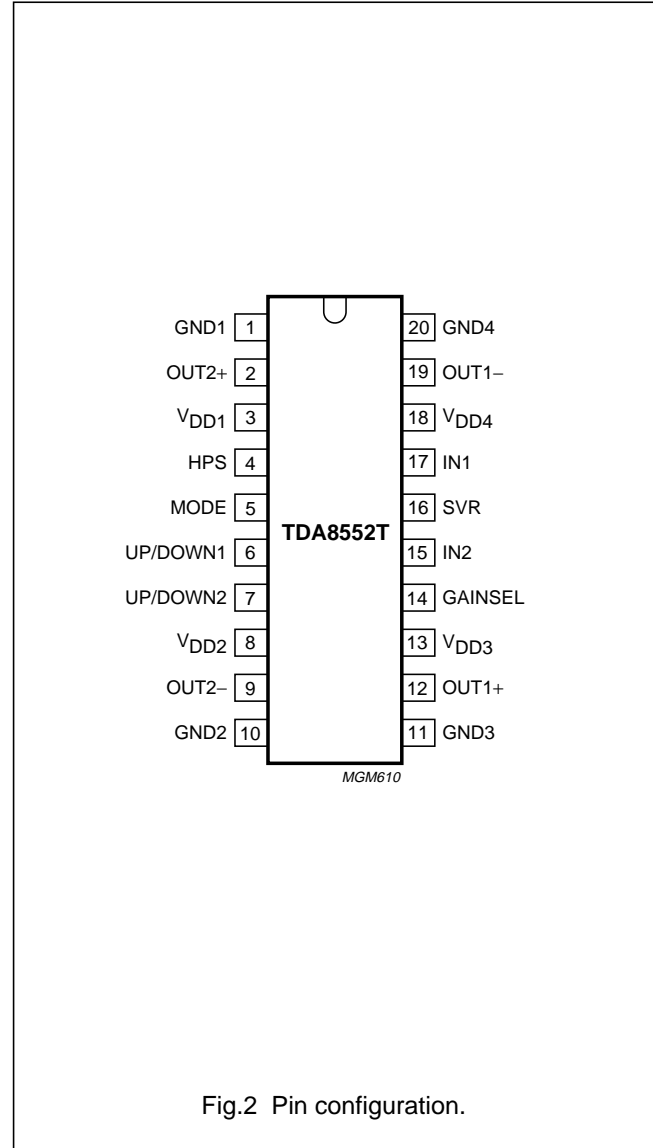

Fig.2 Pin configuration.

Note

1. For the SO20 (SOT163-1) package only: the ground pins 1, 10, 11 and 20 are mechanically connected to the leadframe and electrically to the substrate of the die. On the PCB the ground pins can be connected to a copper area to decrease the thermal resistance.

2 × 1.4 W BTL audio amplifiers with digital volume control and headphone sensing

TDA8552T; TDA8552TS

FUNCTIONAL DESCRIPTION

The TDA8552T is a 2 × 1.4 W BTL audio power amplifier capable of delivering 2 × 1.4 W output power into an 8 Ω load at THD = 10% using a 5 V power supply. The gain of the amplifier can be set by the digital volume control. The gain in the maximum volume setting is 20 dB (low gain) or 30 dB (high gain). This maximum gain can be selected by the gain selection pin. The headphone sense input (HPS) can be used to detect if a headphone is plugged into the jack connector. If a headphone is plugged into the jack connector the amplifier switches from the BTL to the SE mode and the BTL loudspeakers are switched off. This also results in a reduction of quiescent current consumption. Using the MODE pin the device can be switched to the standby condition, the mute condition or the normal operating condition. The device is protected by an internal thermal shutdown protection mechanism.

Power amplifier

The power amplifier is a Bridge-Tied Load (BTL) amplifier with a complementary CMOS output stage. The total voltage loss for both output power MOS transistors is within 1 V and with a 5 V supply and an 8 Ω loudspeaker an output power of 1.4 W can be delivered. The total gain of this power amplifier can be set at 20 or 30 dB by the gain selection pin.

Gain selection

The gain selection can be used for a fixed gain setting, depending on the application. The gain selection pin must be hard wired to ground (20 dB) or to V_{DD} (30 dB). Gain selecting during the operation is not advised, switching is not guaranteed plop free.

Input attenuator

The volume control operates as a digitally controlled input attenuator between the audio input pin and the power amplifier. In the maximum volume control setting the attenuation is 0 dB and in the minimum volume control setting the typical attenuation is 80 dB. The attenuation can be set in 64 steps by the UP/DOWN pin. Both attenuators for channels 1 and 2 are separated from each other and are controlled by their own UP/DOWN pin. Balance control can be arranged by applying UP/DOWN pulses only on pins 6 and 7, see Fig.5.

Volume control

Each attenuator is controlled with its own UP/DOWN pin (trinary input):

- Floating UP/DOWN pin: volume remains unchanged
- Negative pulses: decreasing volume
- Positive pulses: increasing volume.

Each pulse on the UP/DOWN pin results in a change in gain of $\frac{80}{64} = 1.25$ dB (typical value).

In the basic application the UP/DOWN pin is switched to ground or V_{DD} by a double push-button. When the supply voltage is initially connected, after a complete removal of the supply, the initial state of the volume control is an attenuation of 40 dB (low volume), so the gain of the total amplifier is -20 dB in the low gain setting or -10 dB in the high gain setting. After powering-up, some positive pulses have to be applied to the UP/DOWN pin for turning up to listening volume.

Auto repeat

If the UP/DOWN pin is LOW or HIGH for the wait time (t_{wait} in seconds) (one of the keys is pressed) then the device starts making up or down pulses by itself with a frequency given by $\frac{1}{t_{rep}}$ (repeat function).

The wait time and the repeat frequency are set using an internal RC oscillator with an accuracy of ±10%.

Volume settings in standby mode

When the device is switched with the MODE select pin to the mute or the standby condition, the volume control attenuation setting keeps its value, under the assumption that the voltage on the V_{DD} pin does not fall below the minimum supply voltage. After switching the device back to the operation mode, the previous volume setting is maintained. In the standby mode the volume setting is maintained as long as the minimum supply voltage is available. The current consumption is very low, approximately 1 μA (typ.). In battery fed applications the volume setting can be maintained during battery exchange if there is a supply capacitor available.

2 × 1.4 W BTL audio amplifiers with digital volume control and headphone sensing

TDA8552T; TDA8552TS

Mode select pin

The device is in the standby mode (with a very low current consumption) if the voltage at the MODE pin is between V_{DD} and $V_{DD} - 0.5$ V. At a mode select voltage level of less than 0.5 V the amplifier is fully operational. In the range between 1 V and $V_{DD} - 1$ V the amplifier is in the mute condition. The mute condition is useful for using it as a 'fast mute', in this mode the output signal is suppressed, while the volume setting remains at its value. It is advised to keep the device in the mute condition while the input capacitor is being charged. This can be achieved by holding the MODE pin at a level of $0.5V_{DD}$, or by waiting approximately 100 ms before giving the first volume-UP pulses.

Headphone sense pin (HPS)

A headphone can be connected to the amplifier by using a coupling capacitor for each channel. The common ground pin of the headphone is connected to the ground of the amplifier, see Fig.4. By using the HPS pin as illustrated in Fig.4, the TDA8552T detects if a headphone jack plug is inserted into the connector.

When no headphone is plugged in, the voltage level at the HPS pin will remain LOW. A voltage less than $V_{DD} - 1$ V at the HPS pin will keep the device in the BTL mode, thus the loudspeakers can be operational. If the HPS pin is not connected then the device will remain in the BTL mode.

When a headphone is plugged into the connector, the voltage at the HPS pin will be set to V_{DD} . The device then switches to the Single-Ended (SE) mode, this means that the slave power amplifiers at the outputs OUT1– and OUT2– will be switched to the standby mode. This results in floating outputs OUT1– and OUT2–, the loudspeaker signal is thus attenuated by approximately 80 dB and only the headphone can operate.

One of the benefits of this system is that the loudspeaker current does not flow through the jack connector switch, which could give some output power loss. The other benefit is that the quiescent current is reduced when the headphone jack is inserted.

Z_i	input impedance		14	20	–	$k\Omega$
$V_{i(max)(rms)}$	maximum input voltage (RMS value)		–	–	1.75	V

Notes

- With a load connected at the outputs the quiescent current will increase, the maximum of this increase being equal to $2 \times \left(\frac{\text{DC output offset voltage}}{R_L} \right)$
- The DC output voltage with respect to ground is approximately $0.5V_{DD}$.
- Output voltage in mute position is measured with an input of 1 V (RMS) in a bandwidth of 20 kHz, so including noise, gain select pin is LOW (0 V).

2 × 1.4 W BTL audio amplifiers with digital volume control and headphone sensing

TDA8552T; TDA8552TS

AC CHARACTERISTICS ($V_{DD} = 3.3\text{ V}$)

$T_{amb} = 25\text{ °C}$; $R_L = 8\ \Omega$; $f = 1\text{ kHz}$; total gain setting at 7 dB; $V_{MODE} = 0\text{ V}$; gain select pin is at 0 V (maximum gain = 20 dB); according to Fig.4.

SYMBOL	PARAMETER	CONDITIONS	MIN.	TYP.	MAX.	UNIT
P_o	output power	THD = 10%; $R_L = 4\ \Omega$	–	0.9	–	W
		THD = 10%; $R_L = 8\ \Omega$	–	0.6	–	W

TEST AND APPLICATION INFORMATION

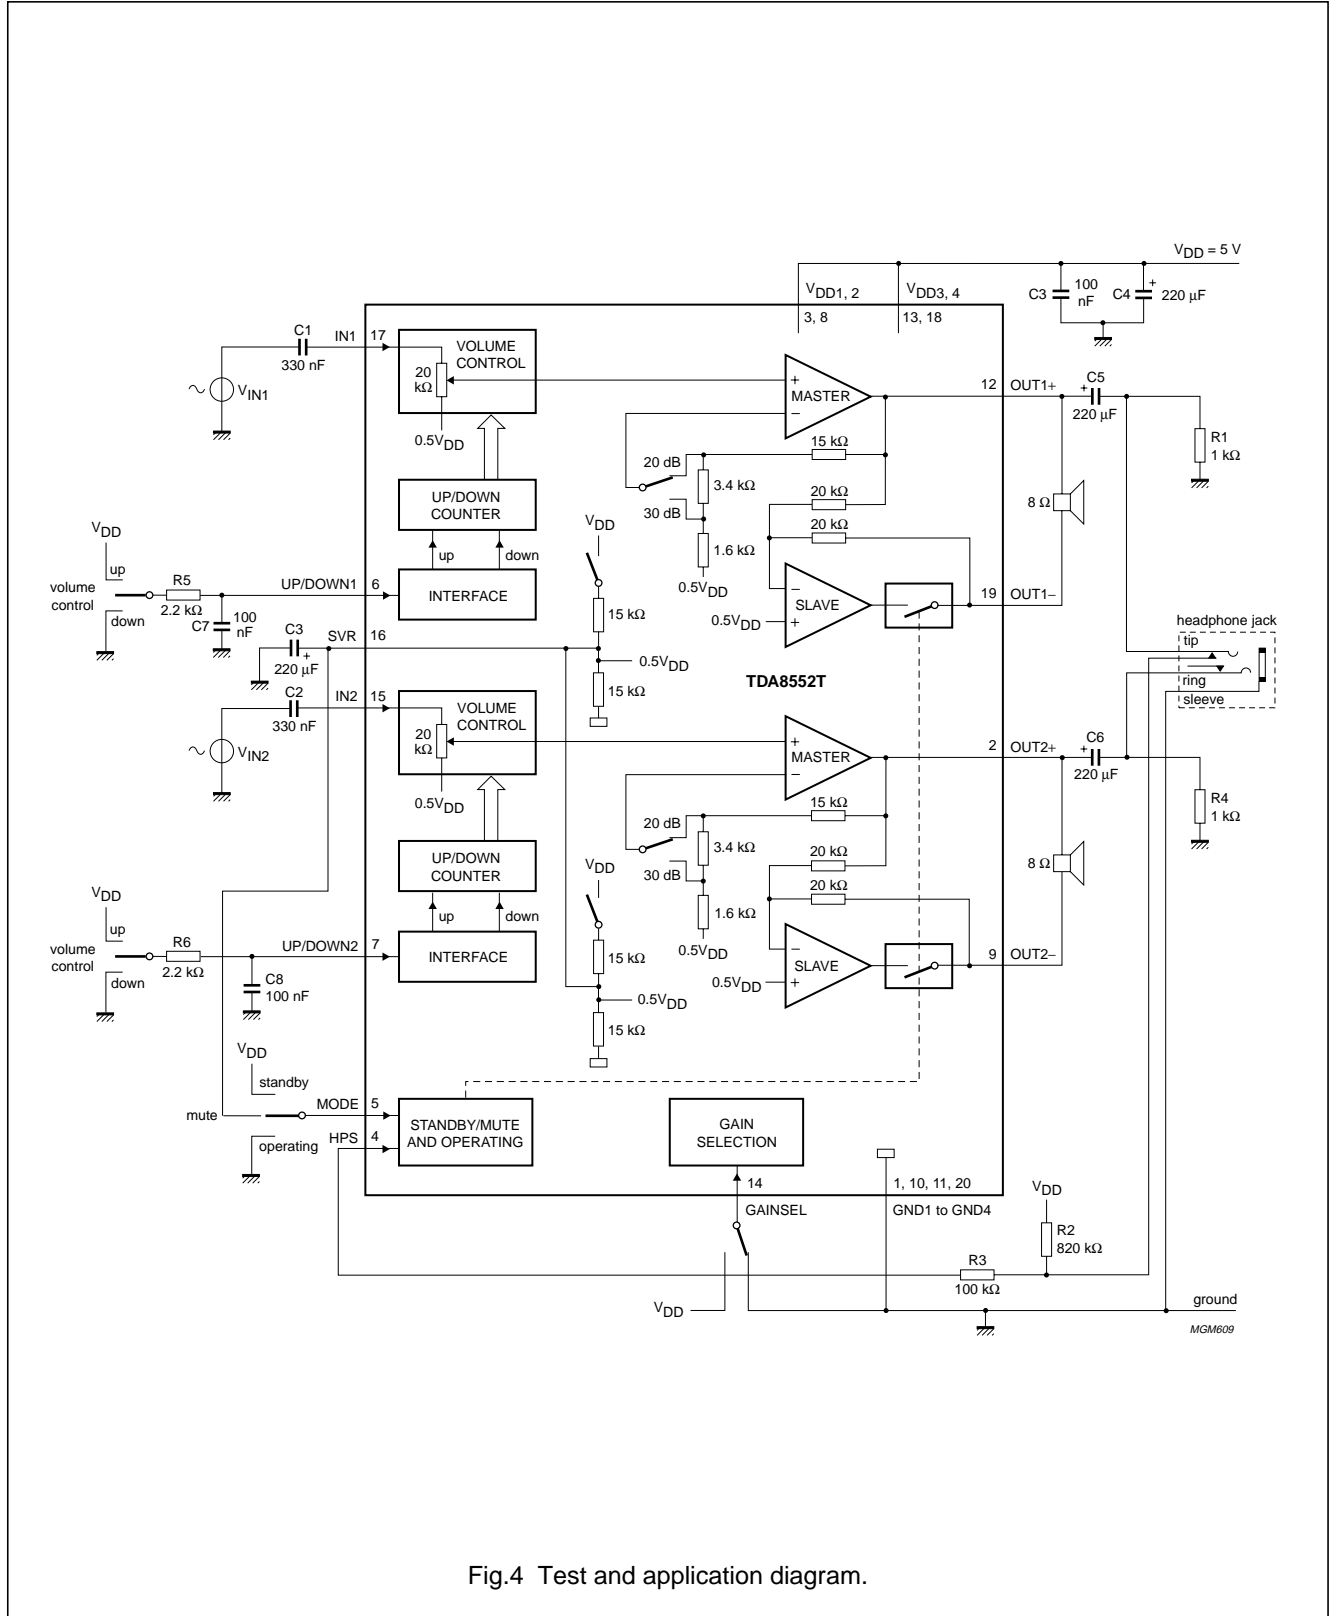

Fig.4 Test and application diagram.

2 × 1.4 W BTL audio amplifiers with digital volume control and headphone sensing

TDA8552T; TDA8552TS

Test conditions

$T_{amb} = 25^{\circ}\text{C}$ if not specially mentioned; $V_{DD} = 5\text{ V}$; $f = 1\text{ kHz}$, $R_L = 8\ \Omega$, $G_v = 20\text{ dB}$, audio band-pass 22 Hz to 22 kHz. The thermal resistance (in standard print, without extra copper) = 110 K/W for the SSOP20; the maximum sine wave power dissipation is:

$$\frac{150 - 25}{110} = 1.14\text{ W}$$

For $T_{amb} = 60\ ^{\circ}\text{C}$ the maximum total power dissipation is:

$$\frac{150 - 60}{110} = 0.82\text{ W}$$

Thermal design considerations

The 'measured' thermal resistance of the IC package is highly dependent on the configuration and size of the application board. All surface mount packages rely on the traces of the PCB to conduct heat away from the package. To improve the heat flow, a significant area on the PCB must be attached to the (ground) pins. Data may not be comparable between different semiconductor manufacturers because the application boards and test methods are not (yet) standardized. Also, the thermal performance of packages for a specific application may be different than presented here, because the configuration of the application boards (copper area) may be different. Philips Semiconductors uses FR-4 type application boards with 1 oz copper traces with solder coating Solder Resist Mask (SRM).

The SSOP20 package has improved thermal conductivity which reduces the thermal resistance. Using a practical PCB layout (see Fig.18) with wider copper tracks to the corner pins and just under the IC, the thermal resistance from junction to ambient can be reduced to approximately 80 K/W. For $T_{amb} = 60\ ^{\circ}\text{C}$ the maximum total power

dissipation for this PCB layout is: $\frac{150 - 60}{80} = 1.12\text{ W}$

The thermal resistance for the SO20 is approximately 55 K/W if applied to a PCB with wider copper tracks to the corner pins and just under the body of the IC.

The maximum total power dissipation for this practical application is:

$$\frac{150 - 60}{55} = 1.63\text{ W}$$

BTL application

The BTL application diagram is illustrated in Fig.4.

The quiescent current has been measured without any load impedance. The total harmonic distortion as a function of frequency was measured with a low-pass filter of 80 kHz. The value of capacitor C3 influences the behaviour of the SVRR at low frequencies, increasing the value of C3 increases the performance of the SVRR.

Headphone application

$T_{amb} = 25^{\circ}\text{C}$ if not specially mentioned, $V_{DD} = 5\text{ V}$, $f = 1\text{ kHz}$, $R_L = 32\ \Omega$, $G_v = 14\text{ dB}$, audio band-pass 22 Hz to 22 kHz.

For headphone application diagram see: Fig.4

If a headphone is plugged into the headphone jack, the HPS pin will switch-off the outputs of the SLAVE output stage, this results in a mute attenuation >80 dB for the loudspeakers. In this condition the quiescent current will be reduced.

General remarks

Reduction of the value of capacitor C3 results in a decrease of the SVRR performance at low frequencies.

The capacitor value of C5 and C6 in combination with the load impedance of the headphone determines the low frequency behaviour.

To prevent against high output currents during inserting the headphone into the headphone jack, resistors of 5.1 Ω have to be connected in series with the SE output lines.

The UP/DOWN pin can be driven by a 3-state logic output stage (microprocessor) without extra external components. If the UP/DOWN pin is driven by push-buttons, then it is advised to have an RC-filter between the buttons and the UP/DOWN pin. Advised values for the RC-filter are 2.2 k Ω and 100 nF. Resistor R4 is not necessary for basic operation, but is advised to keep C6 charged to a voltage of $0.5V_{DD}$. This has the advantage that the pop noise when inserting the headphone plug is minimal. If the headphone sense function (HPS) is not used then the HPS-pin 4 should be hard-wired to ground. This pin should never be left unconnected.

Using double push buttons, the volume step for both channels can be controlled. When for the balance control only a single contact is used, the balance steps are 1.25 dB. If double contacts are used for the balance buttons and the dashed connection is made, then the balance steps are 2.5 dB.

TDA8552T; TDA8552TS

Application without volume control

If pins 6, 7 and 8 are hardwired together the device operates with the volume control setting at maximum.

When the supply voltage is connected and the device is switched from standby to mute or operating for the first time then the gain is ramped up from -20 dB to +20 dB. This takes approximately 5 s.

This maximum gain setting is maintained until the supply voltage drops below the minimum value.

SOLDERING

Introduction

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our "IC Package Databook" (order code 9398 652 90011).

Reflow soldering

Reflow soldering techniques are suitable for all SO and SSOP packages.

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several techniques exist for reflowing; for example, thermal conduction by heated belt. Dwell times vary between 50 and 300 seconds depending on heating method. Typical reflow temperatures range from 215 to 250 °C.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 minutes at 45 °C.

Wave soldering

SO

Wave soldering techniques can be used for all SO packages if the following conditions are observed:

- A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.
- The longitudinal axis of the package footprint must be parallel to the solder flow.
- The package footprint must incorporate solder thieves at the downstream end.

SSOP

Wave soldering is **not** recommended for SSOP packages. This is because of the likelihood of solder bridging due to closely-spaced leads and the possibility of incomplete solder penetration in multi-lead devices.

If wave soldering cannot be avoided, the following conditions must be observed:

- **A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.**
- **The longitudinal axis of the package footprint must be parallel to the solder flow and must incorporate solder thieves at the downstream end.**

Even with these conditions, only consider wave soldering SSOP packages that have a body width of 4.4 mm, that is SSOP16 (SOT369-1) or SSOP20 (SOT266-1).

METHOD (SO AND SSOP)

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Maximum permissible solder temperature is 260 °C, and maximum duration of package immersion in solder is 10 seconds, if cooled to less than 150 °C within 6 seconds. Typical dwell time is 4 seconds at 250 °C.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

Repairing soldered joints

Fix the component by first soldering two diagonally-opposite end leads. Use only a low voltage soldering iron (less than 24 V) applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C. When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320 °C.
